The 2004 Mars Exploration Rover Mission: Evidence for Water and Prospects for Life

Dr. John Grotzinger
October 13, 2005

Produced by and for *Hot Science - Cool Talks* by the Environmental Science Institute. We request that the use of these materials include an acknowledgement of the presenter and *Hot Science - Cool Talks* by the Environmental Science Institute at UT Austin. We hope you find these materials educational and enjoyable.

The 2004 Mars Exploration Rover Mission:

A Martian Eclipse

Short-Timescale Temperature Excursions

Red = hot

Purple = cold

Red to purple
is 2 K (degrees Kelvin)

- Largest temperature variations confined to lowest 100 meters or so
- Appears that temperature perturbations propagate upward

Dust Devils

Interdune Deflation Surface

Modern Mars Analog: Um Asamin

Modern Interdune Depression

Endurance Chemostratigraphy

~ 50 cm

Ratio to surface rock average

Selected Elements in Endurance Crater Rocks

Changes Down Section: Texture

Ontario

Diamond Jenness

- Meridiani environment appears to have been acidic, hypersaline, and only intermittently wet.
- Life exists at such extremes on Earth.
- But Meridiani data suggest potential challenges to origin as well as persistence of life.

Rio Tinto Extremophiles

Andy Knoll

The Good News

- Evidence of any life that might have existed might well be preserved in chemical sediments and concretions.
- Chemical and textural details of Meridiani salts and iron oxides likely to reveal much about environmental history.

- *All this favors Meridiani Planum as a target for sample return.*

Summary

- Rovers have:
 - Operated for over 1200 days
 - Returned over 100,000 images
 - Analyzed dozens of rocks and soils

Summary

- Evidence for water:
 - Mössbauer detection of jarosite
 - Crystal molds, concretions, diagenesis
 - Festoon ripple cross-bedding
 - Stratigraphic succession of environments

Summary

- Prospects for Life:
 - Preservation potential is good
 - But did life originate under such extreme conditions?

Dr. John Grotzinger

**Fletcher Jones Professor of Geology
California Institute of Technology**

John Grotzinger is a field geologist interested in the co-evolution of surficial environments and life on Earth and Mars. His research addresses the chemical development of the early oceans and atmosphere, and the environmental context of early evolution. Field mapping studies are the starting point for more topical laboratory-based studies involving geochemical, paleontological, and geochronological techniques.

Currently, his research is focused on the reconstruction of environmental conditions associated with the Cambrian radiation of animals in Oman, Namibia and Siberia. In 2004, he served as a member of both the Geology and Long Term Planning Groups for the Mars Exploration Rover mission.
